Note: The instructions above are not tested, but should work. The present invention relates generally to the field of marine vessels, and more particularly to marine vessels configured to operate as sailboats. Sailboats are generally made of wood. The weight of the sailboat may be significantly less than the weight of the boat that has a hull and a traditional propulsion engine. In part, this is because a sailboat has no propulsion or internal drive unit, so a sailboat does not have the weight of the structure that houses the propulsion engine. However, prior art sailboats are not robust in that they often require an operator who is able to simultaneously operate the sail and propel the vessel forward. This is an important consideration, especially for sailboats that are used to travel to areas far from port, in rough waters, or on larger bodies of water. In addition, prior art sailboats have significant stability issues, as any movement of the sailboat in the wind may result in the sailboat listing, which is a serious safety issue. Therefore, it is desirable to provide a robust sailboat that is able to operate efficiently and safely, even when used to travel far from port. Oriented immobilization of human serum albumin: immobilization at the air-water interface. Surface-immobilized human serum albumin (HSA) was studied by the electrochemical, spectroscopic and calorimetric techniques. The hydrophobic binding site of albumin was mainly oriented towards the interface in the air/water system. These findings were in good agreement with the observed enhancement of the anodic current peak, which was related to the desorption step of albumin in the presence of electrolyte. The electrochemical and spectroscopic techniques showed that immobilization of albumin increased the stability of this protein. The change of the structure of albumin after immobilization was analyzed by UV and fluorescence spectroscopy. Compared to the free albumin, the immobilized protein had a higher binding constant and
